SWCON253: Machine Learning

Lecture 10 Model Evaluation

Jinwoo Choi
Assistant Professor
CSE, Kyung Hee University

Contents

1. Model Evaluation
2. Training, Test, Validation Sets
3. Holdout Methods (2-Way & 3-Ways)
4. k-Fold Cross-Validation

Model Evaluation

◆ Model Evaluation

- Evaluates the prediction performance of a model
- More specifically, *estimates* the *generalization performance*, i.e., the predictive performance of our model on future (*unseen*) *data*.

◆ Application

1. **Model Test**: Want to *evaluate* the generalization performance of the *developed (final) model* before deploy.
2. **Model Selection**: Want to *increase* the generalization performance *in the development stage* by tweaking the learning algorithm and *selecting the best* performing model from a given hypothesis space.

Training, Test, Validation Sets

◆ Training Set

- Use training set **to train** your model (**model fitting**)

◆ Test Set

- Use test set **only to evaluate** the performance of your final model (**model test**)
- *Caution: Do not use test set (or test result) to modify your model!*

◆ Validation Set

- You can use validation set **to select** best model or hyper-parameters (**model selection**)
 - ★ e.g., in polynomial regression, select the order of the polynomial (i.e., model capacity)
 - ★ e.g., in L1 or L2 regularization, selecting the regularization-weight λ
 - ★ e.g., in SVM, selecting the slack-weight C and/or kernel parameters
 - ★ Note: "best" here means best performing on the validation set, implying the lowest generalization error

Test data를 쓰면 안되니까
Train에서 검증

(2-Way) Holdout Method

◆ The Simplest Model **Test** Technique

- ① *Divide* our available data into two subsets: a *training* and a *test* set.
 - ★ e.g., randomly assign 33% of the data to the test set, or assign 10% if the dataset is relatively large.
- ② *Train* your ML algorithm with the training set.
- ③ *Estimate* the generalization *performance* of the trained model with the *test* set.
- ④ (*Optional*) *Retrain* your ML algorithm with *all* the data, including both the training set and test set.
 - ★ As a rule of thumb, the model will have a better generalization performance if the algorithms uses more informative data.
 - ★ *Do not re-estimate the generalization performance with this retrained model!*

Test data를 그냥 Validation인거 그냥 넘

3-Way Holdout Method

◆ Holdout Method for Model **Selection** (or Hyperparameter Tuning)

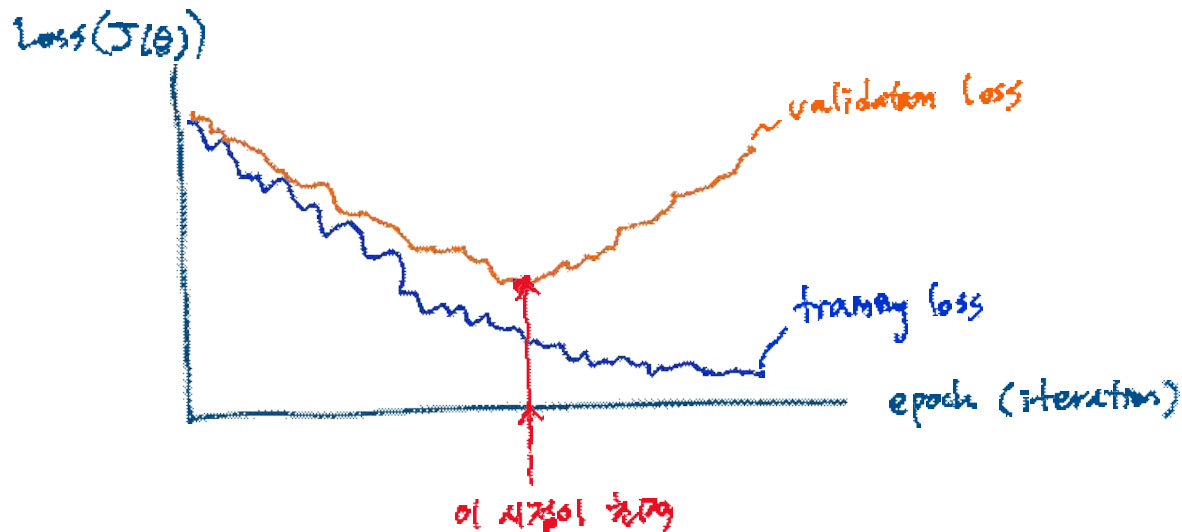

- ① **Divide** our available data into three subsets: a **training**, a **validation**, and a **test** set.
 - ★ e.g., assign 33% of the data to the test set, or assign 10% if the dataset is relatively large.
- ② **Train** your ML algorithm with the same training set but **with different hyperparameter settings**.
- ③ **Compare** the generalization **performance** of the trained models with the **validation** set and **Choose** the **hyperparameters** settings associated with the best performance.
- ④ **Estimate** the generalization **performance** of the trained model with the **test** set.
- ⑤ (**Optional**) **Retrain** your ML algorithm with **all** the data, i.e., including both the training set and test set.

3-Way Holdout Method – Another Usage

◆ Early Stopping to Prevent Overfitting

- Validation Set is extensively used to determine (selecting) model parameters across multiple iterations (epochs)
- A kind of the "3-Way Hold-out Method".

Cross-Validation

◆ Cross-Validation (CV)

- The main idea is that *each sample in our dataset* has the opportunity of being *tested*.
- Cross-validation is very useful when the available *dataset size is small*.
- Cf.) The term cross-validation is used loosely in literature, where the train/test holdout method is sometimes referred to as a cross-validation technique.

Cross-Validation

◆ Cross-Validation (CV)

- ~~Each sample in our dataset~~ *each sample in our dataset* has the opportunity of being *tested*.
- Cross-validation is very useful when the available *dataset size is small*.
- Cf.) The term cross-validation is used loosely in literature, where the train/test holdout method is sometimes referred to as a cross-validation technique.

◆ Leave-one-out cross-validation

◆ k-Fold Cross-Validation

- *k-fold cross-validation* is a special case of cross-validation where we *iterate over a dataset set* times.
→ 테스트(검증)은 안 겹침
- ★ non-overlapping test (validation) folds; *utilizes all data for testing* (validation)
- ★ overlapping training folds → 훈련 데이터는 겹칠수 있음
- It is the most common technique for model evaluation & selection

Model Selection via Validation

- Measure performance on **held-out** training data

→ 샘플

- Simulate testing environment

→ 데이터를 떼는 것 -

- Rotate **folds** of held-out subsets → 평균

- Can even hold out one at a time: **leave-one-out** validation

- Use (cross) validation performance to tune extra parameters

모델 선택 최소: 샘플 1개만 떼어냄

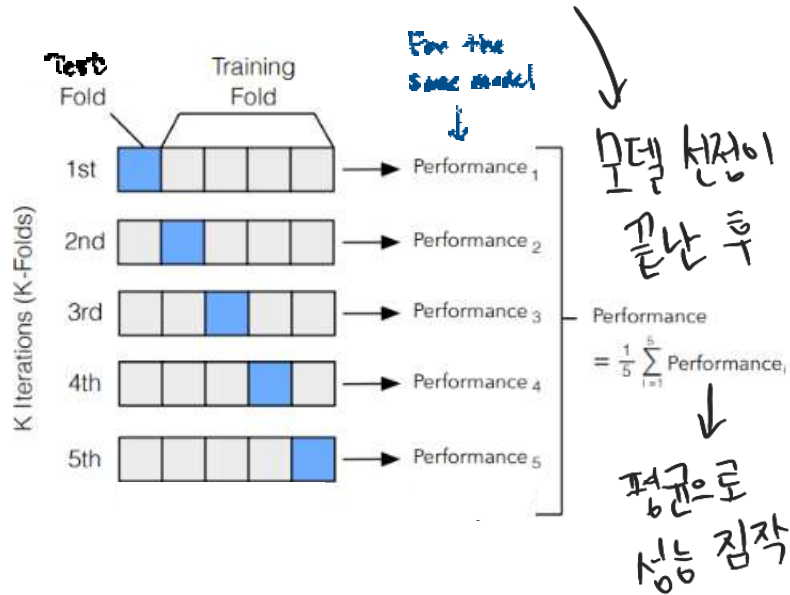

Slide Credit: Bert Huang

k-Fold Cross-Validation

◆ k-Fold CV for Model **Testing** 성능 검증

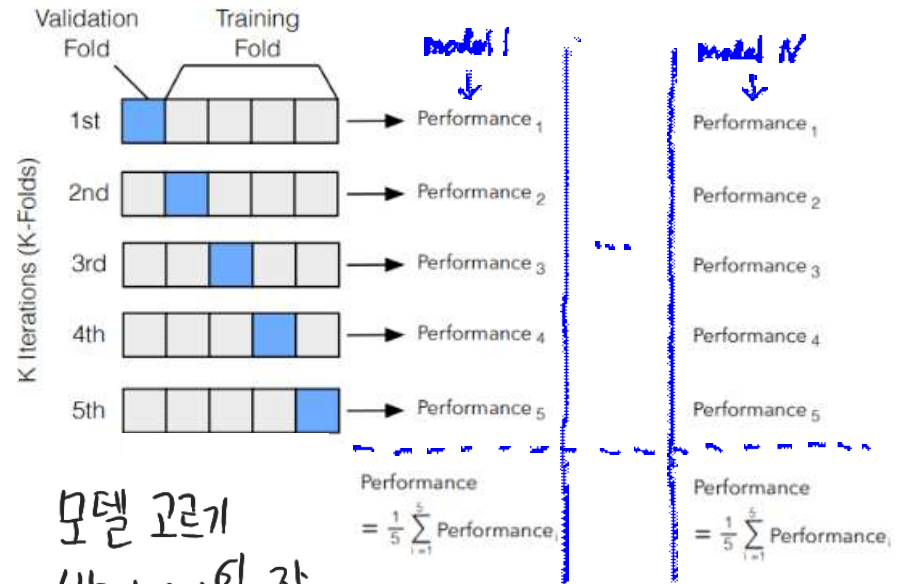

-  given model (with **fixed hyperparameters**).

모델 고르기

◆ k-Fold CV for Model (or Algorithm) **Selection**

- Compare the generalization performance of different models (with **different hyperparameters**).
- Choose the best performing model.

모델 고르기

성능이 제일 잘

나온 모델을 고르겠다. choose the best-performing model
